- Thermodynamics: An Overview
- System, Surrounding and Boundary
- State, Property and Process
- Quasi and Actual Equilibrium
- SI and English Units
- Thermodynamic Properties

Thermodynamics deals with the science of "motion" (*dynamics*) and/or the transformation of "heat" (*thermo*) and energy into various other energy– containing forms. The flow of energy is of great importance to engineers involved in the design of the power generation and process industries. Thermodynamics provides an understanding of the nature and degree of energy transformations, so that these can be understood and suitably utilized.

Disciplines of mechanics:

- Continuum Mechanics (Classical Thermodynamics)
- Quantum Mechanics (Quantum Thermodynamics)
- Statistical Mechanics (Statistical Thermodynamics)

Classical Thermodynamics

- assumes that the world is made up of a continuum is the observational science dealing with heat and work
- is developed based on empirical observations
- describes macroscopic quantities, such as heat, work, internal energy, enthalpy, entropy, Gibbs free energy, etc.
- does not contain any information about the state or even existence of molecules!

Quantum Thermodynamics

- deals with microscopic properties, i.e., length scales on the order of 10e-9 m.
- is based on the idea that every particle behaves as a wave and vice versa
- is not continuous, but discrete!
- Is limited to isolated molecules or perfect crystals, usually at absolute zero temperature
- does not tell us anything about the thermodynamics of a macroscopic system

Statistical Thermodynamics

- *is the bridge between quantum mechanics and continuum*
- deals with individual molecules
- averages properties, energy levels, and probabilities of individual molecules

A **system** is a region containing energy and/or matter that is separated from its surroundings by arbitrarily imposed walls or boundaries. In a thermodynamic analysis, the **system** *is* the subject of the investigation.

A **boundary** is a closed surface surrounding a system through which energy and mass may enter or leave the system.

Everything external to the *system* is the *surroundings*.

closed system (control mass): energy, but not matter, can be exchanged with the environment.

Examples: a cup of coffee with a lid.

open system (control volume): Both energy and matter can be exchanged with the environment.

Example: a cup of coffee without a lid.

isolated system: Neither energy nor mass can be exchanged with the environment. In fact, no interactions with the environment are possible at all. Example: coffee in a closed, well-insulated thermos bottle.

The condition of a system at any instant of time is called its *state*. The state at a given instant of time is described by the *properties* of the system.

A *property* is any quantity whose numerical value depends on the state but not the history of the system. The value of a property is determined in principle by some type of physical operation or test.

Extensive properties depend on the size or extent of the system. Volume, mass, energy and entropy are examples of extensive properties. An extensive property is additive in the sense that its value for the whole system equals the sum of the values for its parts.

Intensive properties are independent of the size or extent of the system. Pressure and temperature are examples of intensive properties.

Two states are identical if, and only if, the properties of the two states are identical. When any property of a system changes in value there is a change in state, and the system is said to undergo a *process*.

Phase and Pure Substance

The term **phase** refers to a quantity of matter that is homogeneous throughout in both chemical composition and physical structure. Homogeneity in physical structure means that the matter is all *solid*, or all *liquid*, or all *vapor* (*gas*). A system can contain one or more phases.

A *pure substance* is one that is uniform and invariable in chemical composition. *A* pure substance can exist in more than one phase, but its chemical composition must be the same in each phase. For example, if liquid water and water vapor form a system with two phases, the system can be regarded as a pure substance because each phase has the same composition. **Equilibrium** means a condition of balance. In thermodynamics the concept includes not only a balance of forces, but also a balance of other influences. Each kind of influence refers to a particular aspect of thermodynamic (complete) equilibrium.

Thermal equilibrium = an equality of temperature *Mechanical equilibrium* = an equality of pressure *Phase* or *Chemical equilibrium* = an equality of chemical potentials

For *thermodynamic equilibrium* the several types of equilibrium must exist individually.

To determine if a system is in thermodynamic equilibrium, isolate the system from its surroundings and watch for changes in its properties. If there are no changes, it may be concluded that the system was in *equilibrium* at the moment it was isolated.

Quasi-equilibrium process means the departure of the system from a thermodynamic equilibrium is infinitesimal.

International System of Units (SI) and English Units

	SI	English
Mass	kg	lb
Length	m	ft
Time	S	S
Temperature	С	F
	SI	English
Velocity = Distance/Time	m/s	ft/s
Force = Mass*Acceleration	Ν	lbf
Pressure = Force / Area	N/m² (Pa)	lbf/ft ²
Work or Heat = Force*Distance	J	BTU

Thermodynamic Properties

Temperature

Units: Kelvin, Rankine Fahrenheit, and Celsius

 $T(K) = T(^{\circ}C) + 273.15$ $T(^{\circ}R) = 1.8T(K)$ $T(^{\circ}F) = T(^{\circ}R) - 459.67$ $T(^{\circ}F) = 1.8T(^{\circ}C) + 32$
